

# Fire, Land Cover and Climate Change: Impacts on River Flows in Semiarid Shrubland Watersheds

San Diego State University

**How do fire regimes and modifications to these regimes effect river flow characteristics in chaparral dominated ecosystems?**

**A goal is to investigate the interaction between climate change, fire regimes and river flow characteristics**

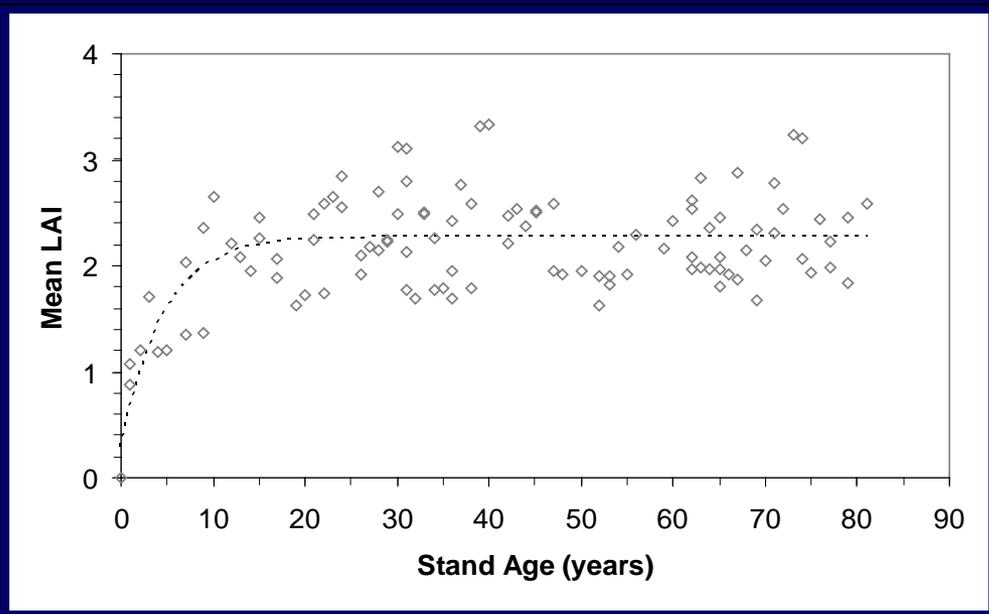

# CHAPARRAL POST FIRE LAI PATTERNS USING THEMATIC MAPPER NDVI DATA

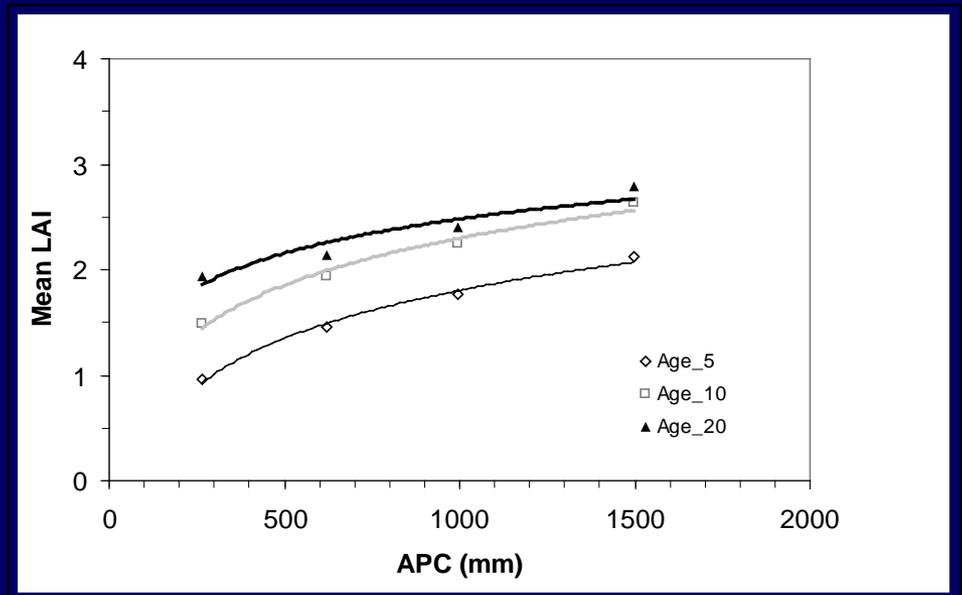

- A carefully intercalibrated time series of Thematic Mapper images (N=25) has been developed and used to derive post-fire LAI recovery trajectories. These trajectories have been shown to be suitable inputs for hydrologic models (e.g., MIKE-SHE) and for calibrating coupled carbon and hydrologic models (e.g., RHES Sys).

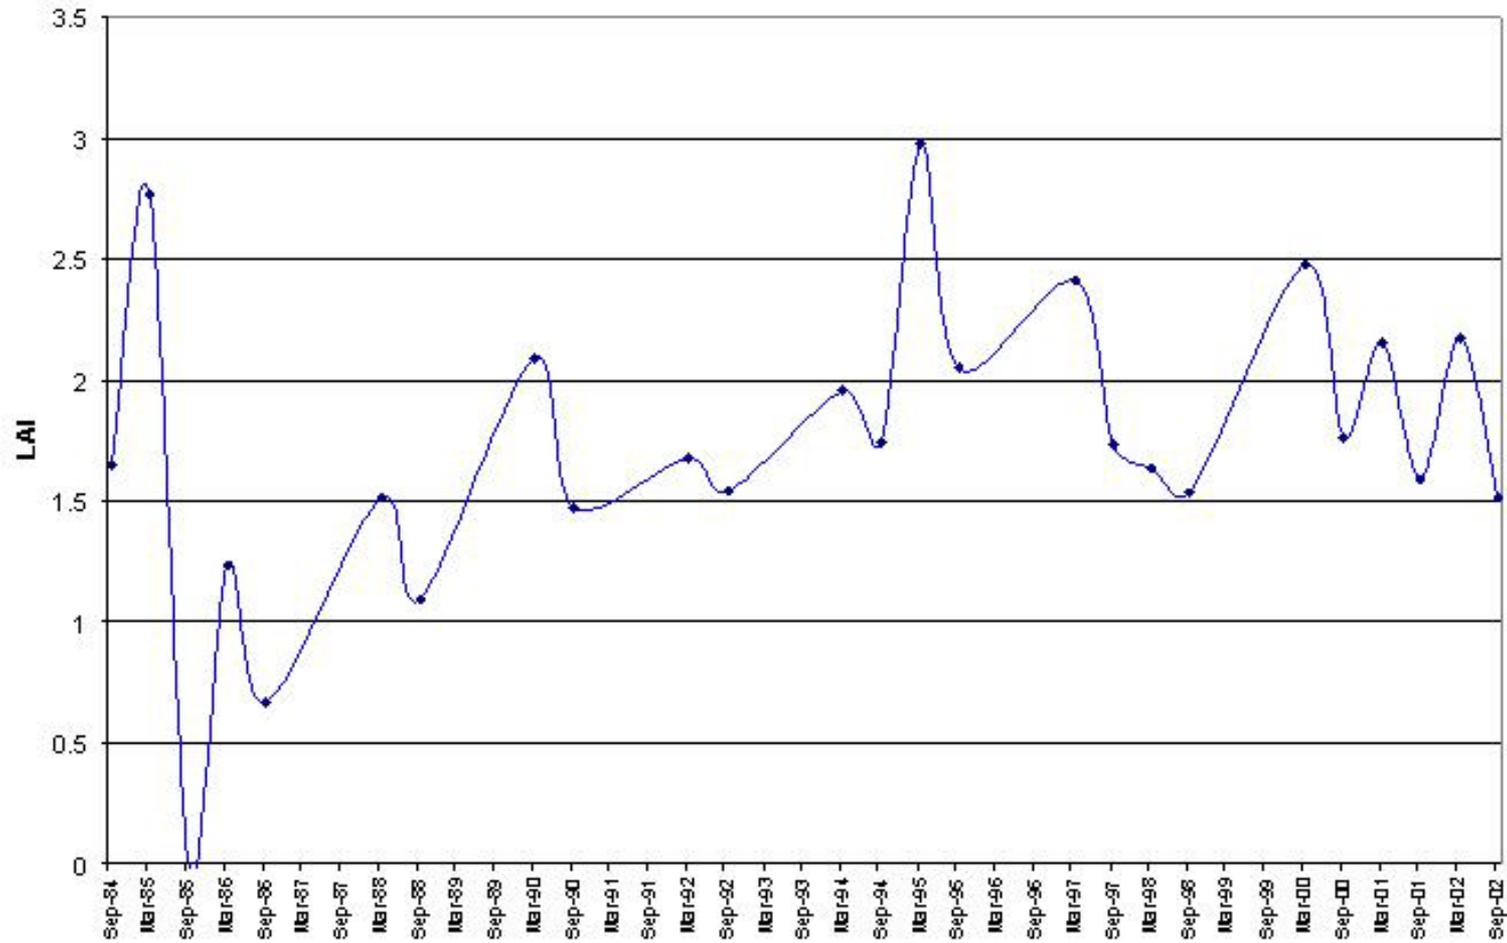

**LAI Stand Age Relationship**  
**Thematic Mapper**  
**Chronosequence Approach**

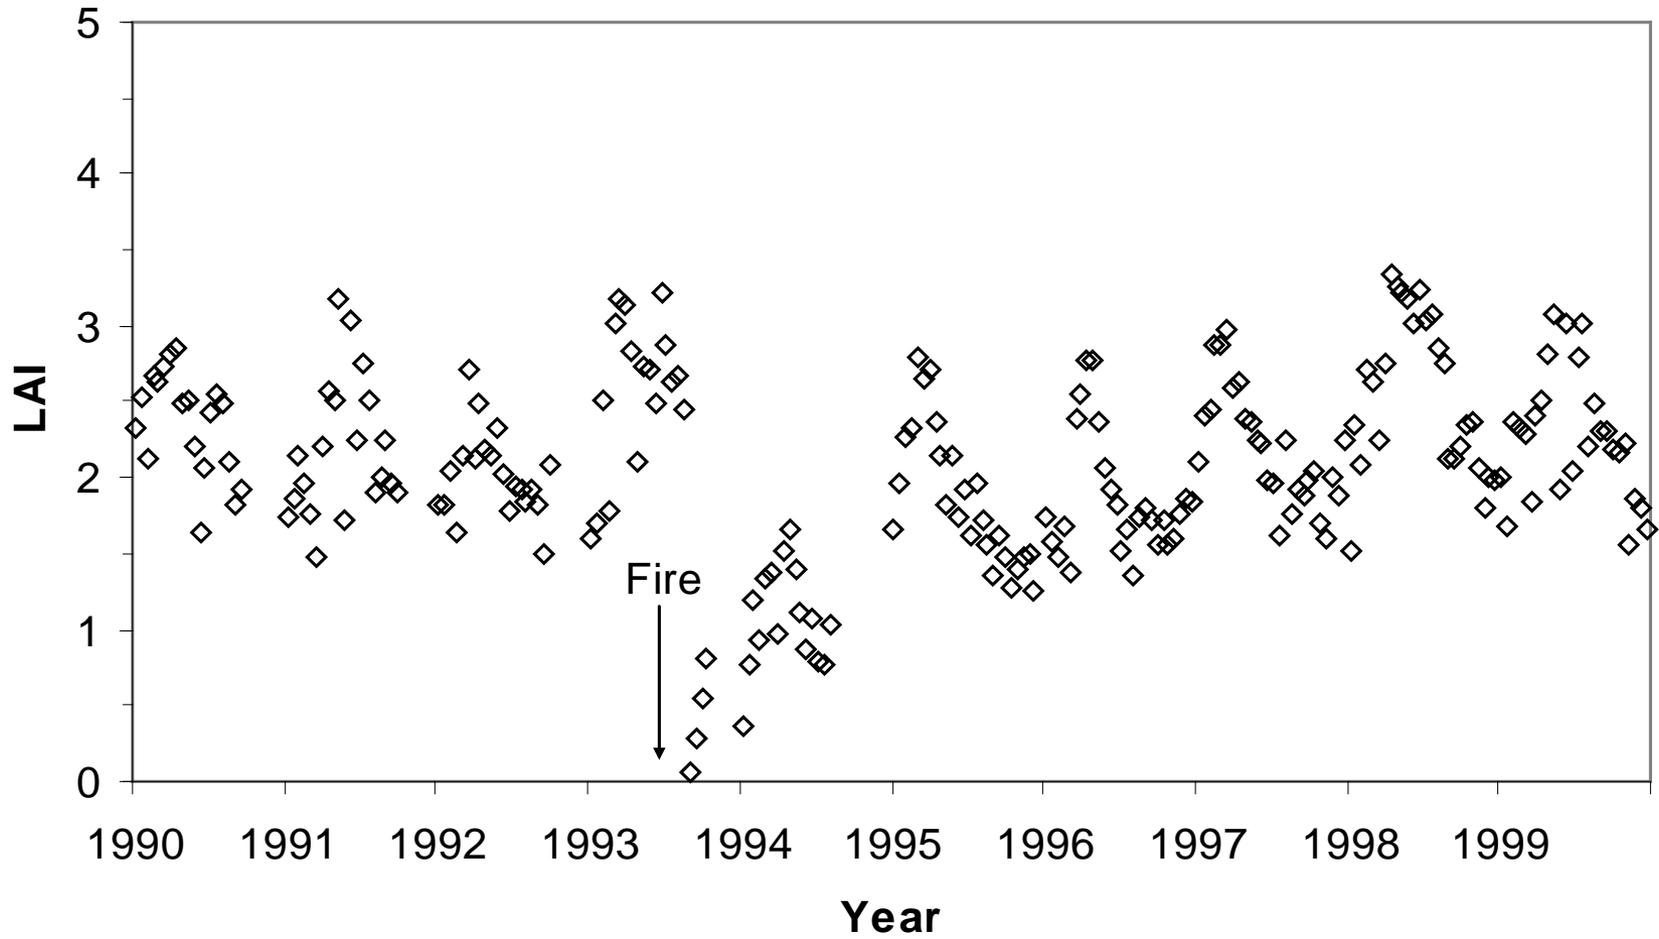

**LAI Antecedent**  
**Precipitation**  
**Relationship**

## Jameson average LAI – from TM/ETM NDVI data

# AVHRR

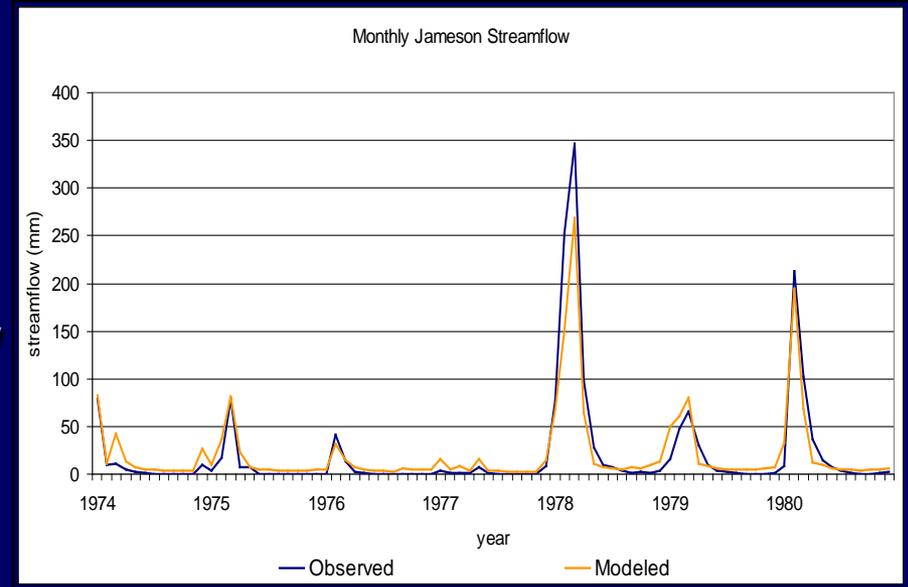

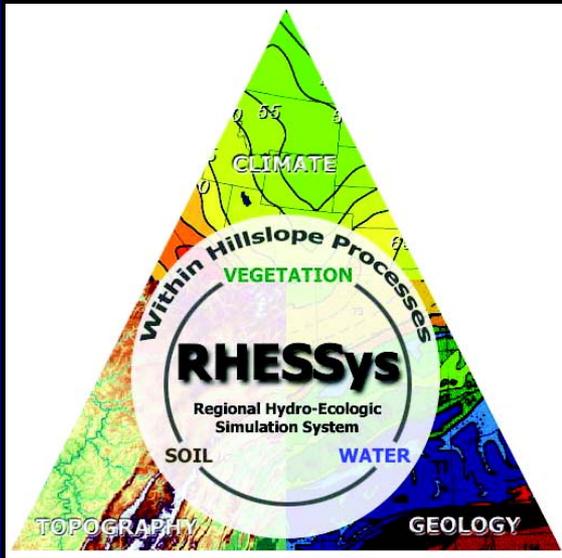

# BI-VARIATE MODEL CALIBRATION

- Bi-variate calibration of RHESSys (gaged streamflow, satellite-derived LAI) has been successful following adaptations to the model and with a priori knowledge of vegetation type. Spatial patterns of LAI provided by Thematic Mapper data provides a means to validate modeled internal watershed conditions such as soil moisture and vegetation production.

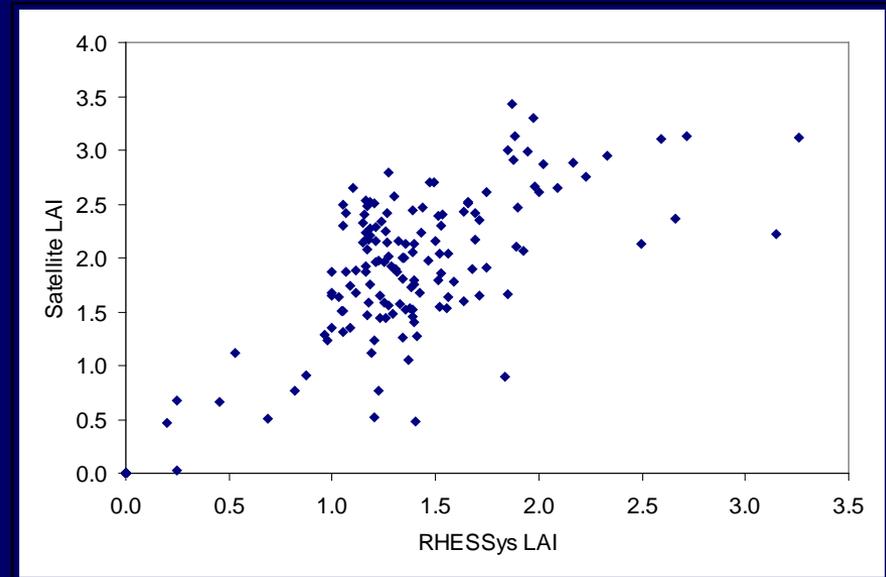

# Bi-variate calibration

Monthly  
Streamflow

LAI  
(540m resolution)

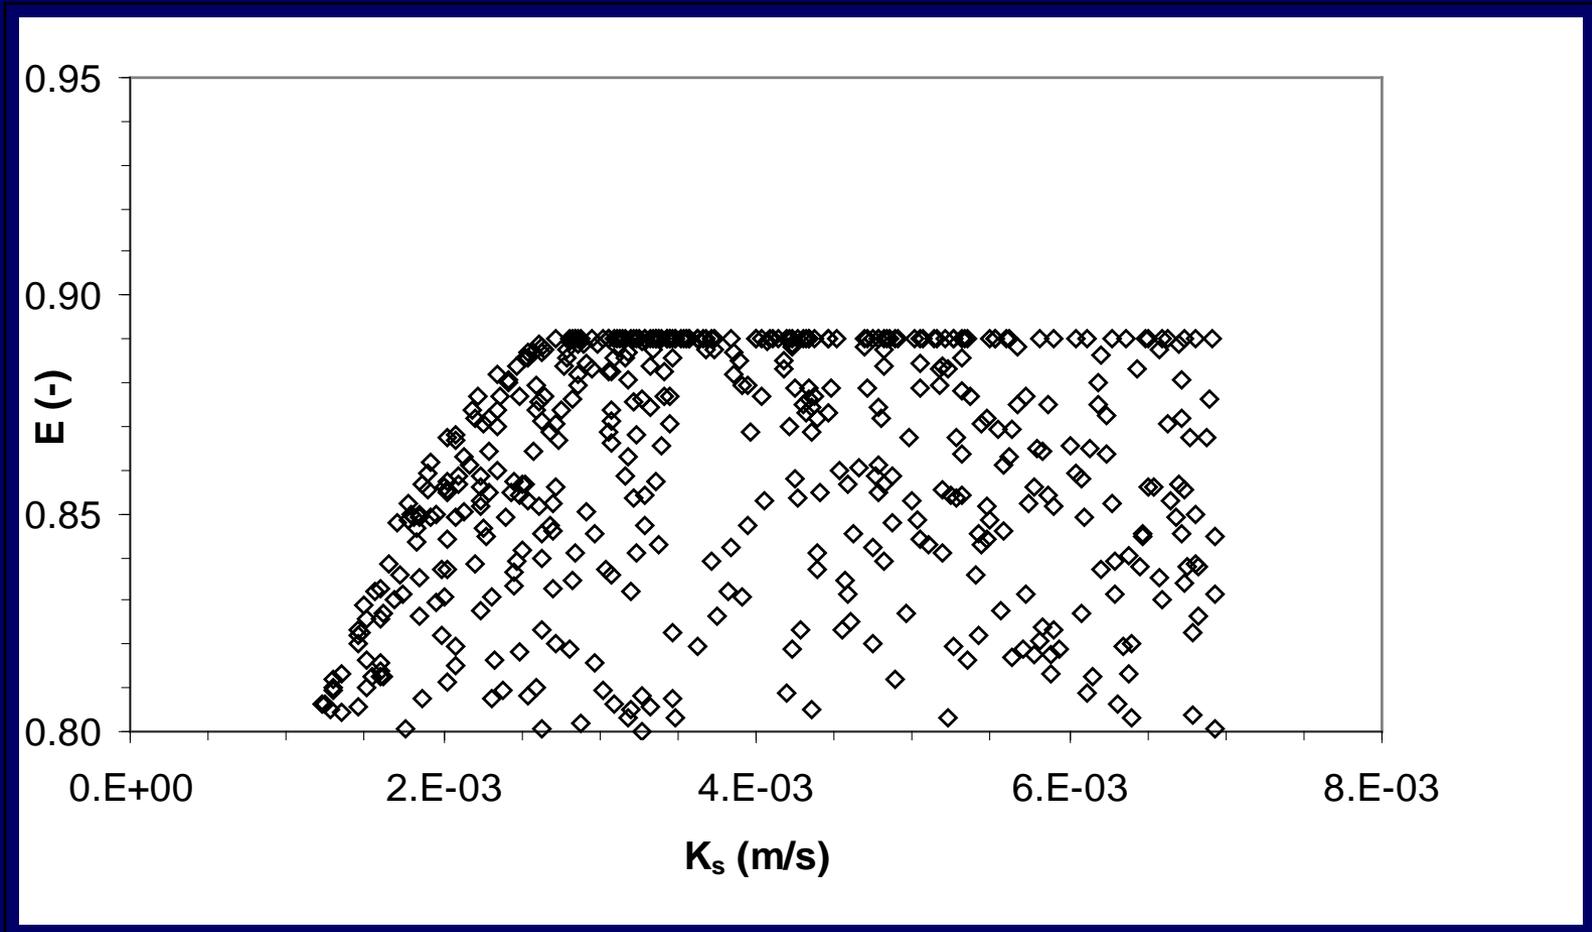

# MODEL UNCERTAINTY

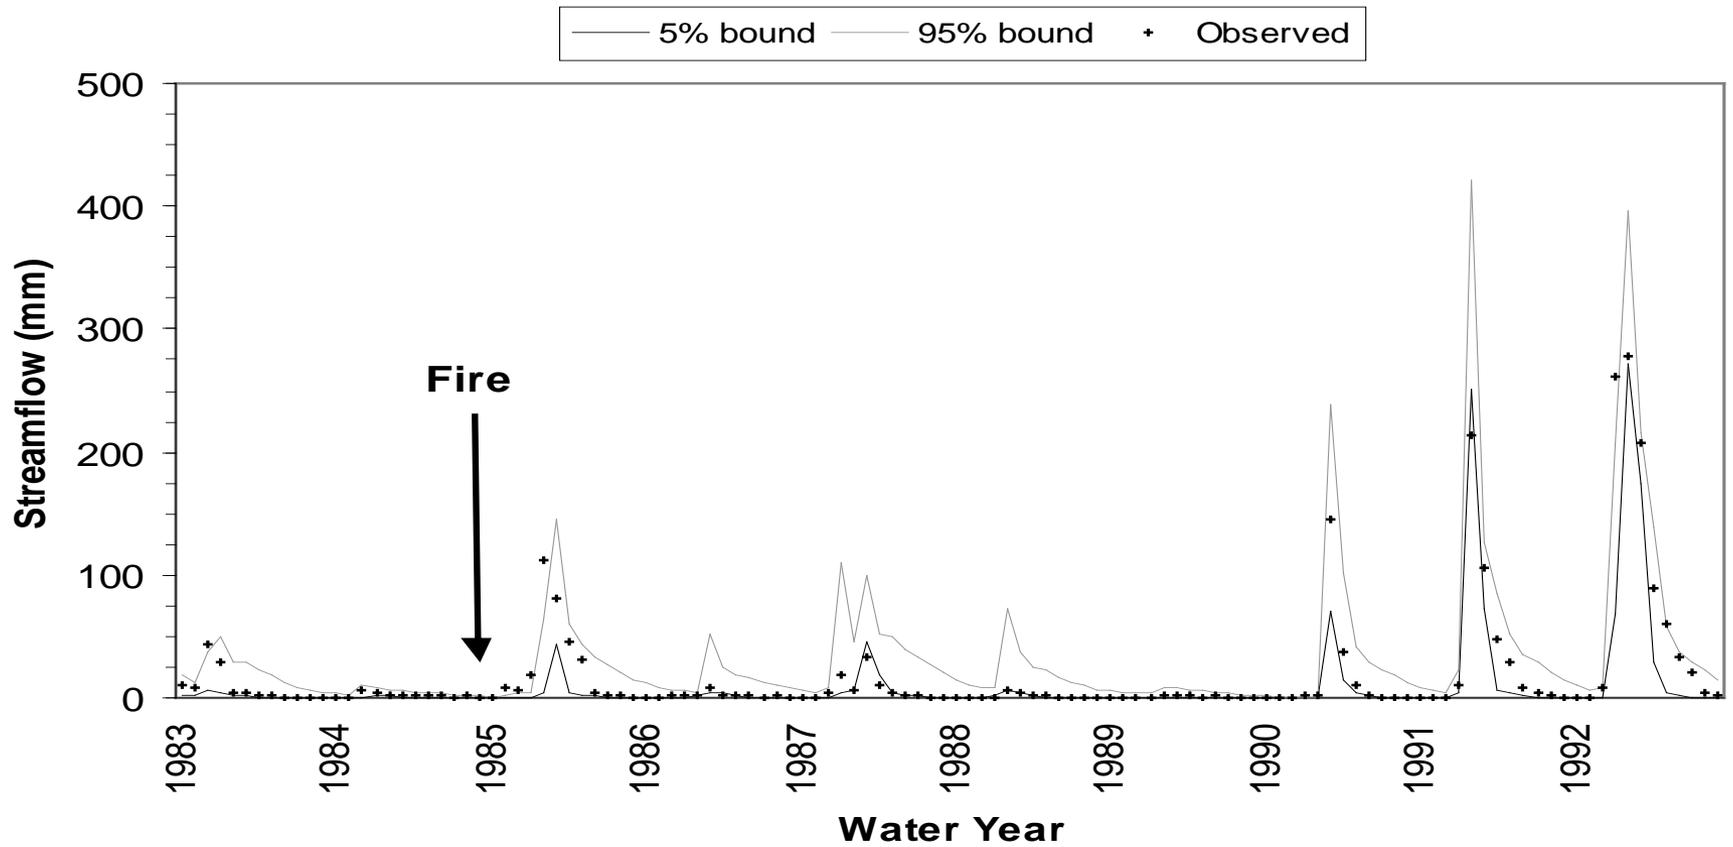

- Parameter equifinality gives rise to uncertainty in hydrologic and coupled carbon-hydrologic models and can be addressed using the Generalized Likelihood Uncertainty Estimator (GLUE) methodology. Spatial heterogeneity in land cover type is the primary source of uncertainty in modelled LAI.

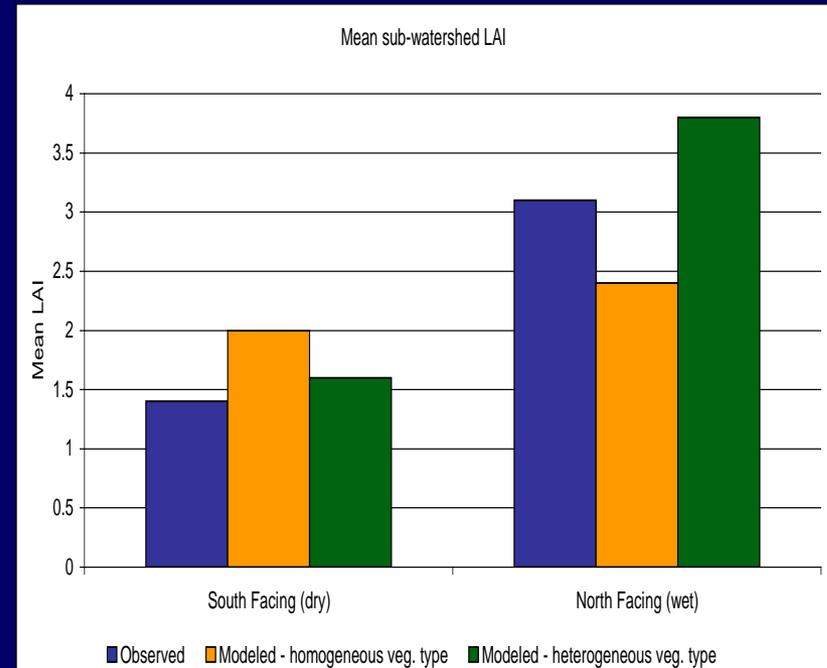

# Coefficient of efficiency (observed vs. modeled streamflow) for range of RHESSys saturated hydraulic conductivity

# MIKE-SHE streamflow simulation with GLUE uncertainty bounds

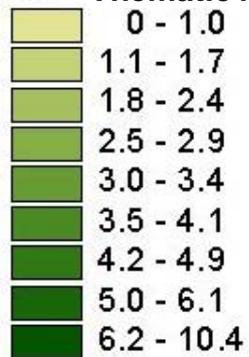

# Implications of heterogeneity within Northern Mixed Chaparral - the presence of riparian oaks is significant for simulating river flows and LAI

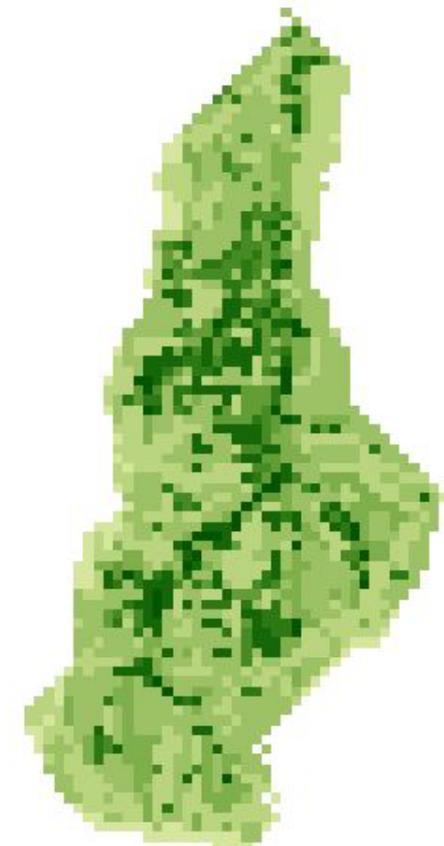

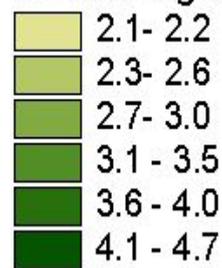

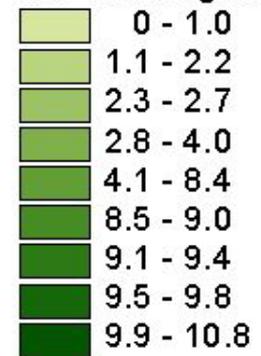

LAI - Thematic Mapper

LAI - homogeneous

LAI - heterogeneous

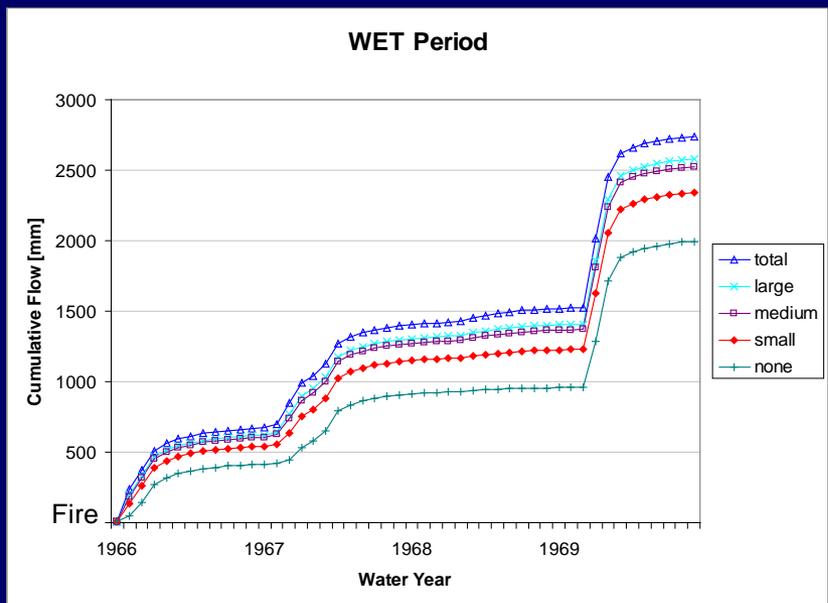

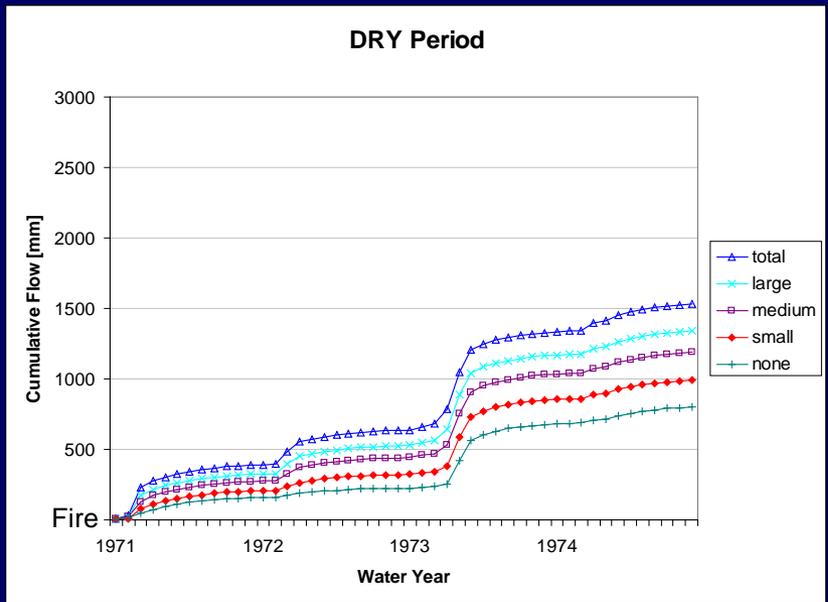

# HYDROLOGIC RESPONSE TO FIRE

- Results based on the calibrated MIKE-SHE model indicate that there is a systematic relationship between the area burnt in a watershed and the resulting increase in river flow in the first 4 – 5 years after fires. The absolute change in river flow is similar for wet and dry periods, but represents a larger fraction in the dry period flows.

# MIKE-SHE simulated streamflow following fire

(for range of fire sizes)

# Methodological Outcome

Robust research methodology for application in other watersheds/regions and for land use/land cover change/climate change scenarios:

- Thematic Mapper NDVI-LAI approach.
- Model calibration based on river hydrograph and satellite-derived

LAI.

Formally address parameter equifinality.
